Abstract

Bacterial endotoxin (lipopolysaccharide, LPS) and interleukin 2 (IL-2) are known to stimulate NK cell mediated cytotoxicity against tumor cells. In the present report we sought to correlate the stimulatory effect of IL-2 and LPS on NK cells with ultrastructural changes which occurred as a result of such stimulation. Peripheral blood mononuclear cells (PBMC) were purified from healthy donors by a Ficoll-Hypaque density gradient technique. Leu-11* NK cells were isolated by flow microfluorometry using a monoclonal FITC conjugated anti-Leu-lla antihody and a FACS II cell sorter. The PBMC were incubated respectively with E. coli LPS or recombinant IL-2 (rIL-2) for various time periods. Sorted Leu-11 NK cells were incubated with LPS for The NK cytotoxicity contained within the PBMC and sorted Leu-II+ cells was assessed by a 51Cr release technique using K562 tumor cells as targets. Resumble to Leu-11* NK cells were identified by immunoelectron microscopy using anti-Leu-lla antibody and labelling

89 11 50 075

with horseradish peroxidase or colloidal gold. Results showed that both LPS and rIL-2 significantly enhanced the cytotoxic activity of PBMC and sorted Leu-11 cells. LPS also stimulated in vitro production of interferon in the PBMC and caused ultrastructural alterations in Leu-II+ cells. morphological changes in Leu-II+ cells included increase of dense granules and small vesicles, dilation of the cisternae of rough endoplasmic reticulum and nuclear enevelope, and increased acid phosphatase activity. Recombinant IL-2 induced a significant increase in the number of dense granules, hypertrophy of Golgi apparatus and rough endoplasmic reticulum, and cell proliferation in Leu-11 cells 7 days after stimulation. These data suggest that: (1) both LPS and rIL-2 activate human NK cell mediated cytotoxicity against K562 tumor cells; (2) the effect of LPS on the enhancement of NK cytotoxicity in PBMC may be a direct and/or indirect process involving production lymphokines, such as gamma interferon; (3) LPS has a direct effect on Leu-II+ cells; and (4) the LPS or rIL-2 induced ultrastructural changes in Leu-II* cells correlate directly with the enhanced NK cytotoxicity.

Introduction

Natural killer (NK) cells are defined as a population of lymphoid cells that mediate spontaneous cytotoxicity against neoplasms and against exogenous intruders, such as viruses, bacteria, and parasites. More

recent evidence indicates that NK cells also play a significant role in regulation of the growth and functions of hemopoetic and lymphoid cells. Thus, the studies on NK cells have become a major aspect of immunologic

research since they were dis- recent covered over a decade ago.

NK cells have been found in a antibodies including (sipunculids, annelids, cytoplasm containing LGL are active NK cells (Timonen 1984). et al., 1982). sent heterogenous population of cells with varied phenotypes and functional capabilities.

Various surface characteristics and antigens in human LGL have been observed (Allavana and Ortaldo. 1986). Among these surface markers, HNK-1 (Leu-7) and NKP-15 (Leu-11) are the most important markers and have been broadly used to identify human NK cells in the peripheral blood, tissue fluids, and tissues. The

development of the commercially available monoclonal against Leu-7 wide variety of animal species Leu-II antigens permits extensive invertebrates studies on the morphologic and arthro- functional properties of human NK pods) and the majority of ver- cells. Recent studies using two-(Savary and Lotzva, color flow cytometry show that 1986). In man, NK activity is human NK cells express various associated with a subset of large combinations of Leu-7 and Leu-11 granular lymphocytes (LGL) which antigens (Lanier et al., 1983). NK are characterized by having Fc cells with Leu-7-/Leu-11+ phenoreceptors for IgG and abundant type have been found to be the numerous most potent effector cells azurophilic granules (Timonen et human peripheral blood, whereas al., 1981; Saksela et al., 1979; the Leu-7+/Leu-11" subset is the Herberman et al., 1979). Func- least effective (Lanier et al., tionally only up to about 80% of 1983, 1984; Phillips and Babcock, Using an immunogold and This finding immunoperoxidase double-labelling clearly indicates that LGL repre- method, we have found that human peripheral blood lymphocytes contain approximately 5% Leu-7+/Leu- # 11,15%Leu-7,/Leu-11, and 9%Leu-7, Leu-II NK cells (Kang et al., 1987a).

> Lymphokines including interferons (IFN) and interleukin-2 (IL-2) have been shown to augment the cytotoxic activity of NK cells (Djeu et al., 1979; Ortaldo et al., 1984; Svedersky et al., 1984; Weigent et al., 1983). In addition, bacterial endotoxin (lipopolysaccharide, LPS) has also

been reported to enhance NK cytotoxicity (Fink et al., 1984; Gangemi et al., 1980; Nowotny, However, the mechanisms 1985). by which LPS and II-2 exert their effect on the enhancement of NK activity remain unclear. In the present report, we studied the effect of LPS and IL-2 on the ultrastructure of Leu-11+ NK cells by immunoelectron microscopy and sought to correlate these changes with the observed changes in NK cell funtion occurring as a result of, this stimulation.

Materials and Methods Cell preparation

Peripheral blood monuclear cells (PBMC) were obtained by Ficoll-Hypaque centrifugation of heparinized peripheral venous blood from healthy volunteer donors (Boym, 1968). Leu-11+ cells were isolated from PBMC by a FACS II cell sorter using a monclonal anti-Leu-lla antibody conjugated with FITC (Becton-Dickinson Monoclonal Center. Mountain View, CA) according to the method described by Biddison et al. (1981).

Treatment of Cells with LPS and

IL -2

PBMC were suspended at a concentration of 1 x 10⁶ cells per ml in RPMI 1640 supplemented with 10% heat-inactivated pooled human AB serum (Flow Laboratories McLean, VA), 1% glutamine (Gibco Laboratories, Grand Island, NY), 1% penicillin/streptomycin and 2mercaptoethanol at a concentration of 5×10^{-5} M. Cells were incubated in tissue culture flasks (type 25100, Corning Glass Works, Corning, NY) containing a total of 10 ml medium with 10, 50, and 100 ug/ml LPS in a humidified atmosphere containing 5% CO, in air for 24 hr. controls were cultured under the same conditions in the absence of LPS Cells were harvested for ultrastructural and cytochemical examinations, and cytotoxicity assays 24 hr after incubation. supernatants Culture collected for interferon assays.

Purified Leu-lla+ cells were treated with 50 µg/ml LPS in the same manner in microtiter plates at 37°C for 24 hr. Cells were harvested for cytotoxicity assays after incubation.

PBMC were also incubated with recombinant IL-2 (rIL-2)

(Cetus Corporation, Emeryville, CA) at a concentration of 500 International Units (IU) per ml in the same conditions as above for 2 and 7 days. Cells were harvested for immunoelectron microscopic examination and cytotoxicity after assays incubation.

Assay for NK Cytotoxicity

Effector cells were obtained from PBMC which had been washed with RPMI 1640 after incubation with LPS or rIL-2. K562 myeloid cells (American Type Culture Collection, Rockville, MD) were used as target cells for cytolytic assays. Cytotoxicity assays were performed 96-well v-bottom microtiter plates (PGC Scientific, Gaithersburg, MD), and each effector: target (E/T)ratio was performed in triplicat... Target cells were radiolabeled with 240 µCi of $Na^{51}CrO_{\lambda}$ for 60 to 90 min at 37°C, washed 3 times and viable target cells in 50 microliters of medium were added to varying numbers of effector cells (in 100 microliters o f medium). After incubating in the microtiter plates for 4 to 6 hr

at 37°C, 50 microliters of supernatant were removed from each well. In addition, each assay contained target cells incubated with medium alone in the absence of added effector cells (spontaneous release) and target cells incubated in 5% Triton X-100 (maximum release). Percent specific cytotoxicity was calculated as follows:

Percent specific lysis=

Experimental Spontaneous

release(CPM)- release (CPM)

Maximum - Spontaneous

release(CPM) release(CPM)

The cytotoxicity of the purified Leu-lla* cells after 24 hr incubation with LPS was assessed by the same procedure. A duplicate assay was performed 5 weeks later.

Interferon Assays

The supernatant of the culture medium was collected 24 hr following incubation with various doses of LPS. Total interferon was assayed in human KB cells as previously reported (Maheshwari et al., 1980). The titers of interferon were determined against an international standard of human gamma interferon from NIAID, NIH, Bethesda, MD. Immunoelectron Microscopy

All PBMC samples from different experiments and effectortarget conjugates were processed for immunoelectron microscopic identification of Leu-II+ cells according to the procedures described previously (Kang et al., 1985, 1987 a, b). monoclonal anti-Leu-11 and anti - Leu - 7 antibodies used labelling were stained by the reaction product of horseradish peroxidase (HRP) using an ABC method or labeled with 10 or 20 nm colloidal gold via an anti-mouse IgG antibody. Cells labeled with colloidal gold were utilized for acid phosphatase localization (Kang et 1985). The samples were embedded in Epon (Poly/Bed, Polysciences, Warrington, PA) following dehydration in a series of graded ethanol solutions. Ultrathin sections prepared with a diamond knife were briefly stained in lead citrate and examined in a JEOL 100 CX transmission electron microscope.

Rosulte

Enhancement of NK Activity and
Interferon Production by LPS

Results from .the cytotoxicity assays indicate 1.5- to 2fold increases in the NK cytotoxicity of PBMC treated with LPS for 24 hr as compared to the non-LPS treated controls (Table 1). In some cases, the increase in cytotoxicity correlated directly with increase in LPS concentrations. There was a significant increase in NK activity in sorted Leu-II+ cells incubated with 50 ug/ml LPS for 24 hr as compared to freshly isolated Leu-!! cells (p < 0.02) or Leu-II+ cells incubated in vitro for 24 hr in the absence of LPS (p < 0.03) (Table 2).

In parallel to NK cytotoxicity, the total interferon levels in the supernatants of the LPS-treated PBMC showed a significant dose-dependent increase with LPS concentrations (Table 1).

Enhancement of NK Activity by c11-2

A significantly higher percentage of target cells were killed by effectors stimulated with rIL-2 for 2 or 7 days as compared to that of the controls (p < 0.05) (Table 3). As seen in Table 3, after rIL-2 stimulation for 48 hr, almost all of

Ultrastructure and Ultracytochemistry of Leu-11[†] Cells following Exposure to LPS or rIL-2

Two NK subsets bearing Leu-II antigen in human peripheral blood have been reported (Lanier et al., 1983), including Leu-7 /Leu-11 and Leu-7 / Leu-11. There are no differences ultrastructure betwen these two subsets (Kang et al., 1987a). Both subsets have well defined Golgi complex, rough endoplasmic reticulum, numerous mitochondria, many membianebound dense granules, vacuoles, centrioles, parallel tubular arrays (PTA), and paracrystalline arrays (Figs. 1, 2). Some ultrastructural alterations were observed in Leu-II+ cells 24 hr after incubation with LPS. The cisternae of rough endoplasmic reticulum, nuclear envelope and Golgi saccules showed distinct dilation. Numercus small vesicles and many large dense granules were often found in the cytoplasm of Leu-11+ cells treated with 100 µg/ml LPS (Fig.3). Tubuloreticular inclusions (TRI) were observed in the cisternae of rough endoplasmic Leu-11 cells reticulum of

exposed to 50 and 100 µg/ml LPS for 24 hr (Fig. 4). No ultrast-ructural differences were found in the effector-target conjugates between the LPS-treated and control samples. Frequently more than one Leu-II effector cell was seen conjugated to a single target cell (Fig. 5).

Increase of acid phosphatase activity was observed only in Leu-II⁺ cells which were treated with 50 or 100 ug/ml LPS for 24 hr. The reaction product of the enzyme was observed in the Golgi saccules and vesicles, cisternae of rough endoplasmic reticulum and nuclear envelope, dense granules, vacuoles, and vacuoles containing paracrystalline arrays (Fig. 6).

With respect to the effect of rIL-2 on the ultrastructure of Leu-II cells, no discernible changes were observed 48 hr after treatment with rIL-2. However, the number of dense granules was significantly increased in Leu-II cells exposed to rIL-2 for 48 hr as compared to that of nonstimulated cells (p < 0.004). In contrast, there were marked changes observed in the size and uitrastructure of Leu-II cells

following stimulation with rIL-2 for 7 days (Fig. 7). The size of these cells greatly increased (10.0 ± 0.6 µm). Rough endoptasmic reticulum (Fig. 8) and Golgi complex (Fig. 9) became highly hypertrophied (Fig. 8). The number of dense granules increased significantly in the stimulated cells by having 5.7 ±

2.5 granules per cell section as compared to 1.2 ± 0.8 granules per cell section in the unstimutated cells. Mitotic figures were frequently observed in the stimulated Leu-II cells at this stage (Fig. 10).

Discussion

It is well established that interferons (IFN) including gamma interferon (IFN-r) activate NK cell mediated cytotoxicity against tumor cells (Herberman et al., 1979: Lucero al., 1981; Brunda and Davatelis. 1985). the present study, the positive correlation of enhanced NK cytotoxicity with production of IFN suggests that IFN is involved in the enhancement of NK cytotoxicity in PBMC treated with LPS. The effect of IFN on NK cells is also indicated by the formation of TRI in Leu-11 cells. are proven markers o f IFN stimulation in human peripheral blood lymphocytes (Grimley et al., 1985). Production of IFN-r as a result of stimulation with LPS has been shown in T cells following exposure to IL-2 or macrophages stimulation bу (Blanchard et al., 1986). ports have also shown that LGL produce IFN-r following IL-2 stimulation (Trinchieri et al., 1984; Ortaldo et al., 1984; Young and Ortaldo, 1987). In this regard, IL-2 is essential to the production of IFN-r by T

cells or LGL (Handa et al., 1983). In fact, LPS may indirectly induce production of IL-2 by T cells (Simon and Lee, 1985) and LGL (Pistoia et al., 1983) via stimulation with IL-1 which is produced by macrophages/monocytes (Arend et al., 1985; Dinarello et al., 1985; Haeffner-Cavaillon et al., 1984) and LGL (Herman and Rabson, 1984).

In addition to the indirect effect of LPS on the enhancement of NK cytotoxicity, LPS may also exert a direct effect on human NK cells as indicated by the increased NK cytotoxicity of sorted Leu-II cells and our previous observations of the incorporation of LPS by these cells (Kang et al., 1987c).

Elaboration of Golgi apparatus and rough endoplasmic reticulum in Leu-II+ cells following exposure to LPS suggests active synthesis of new possibly for fabrication of dense granules (Farquar et al., 1986) or for production of IFN (Djeu et al., 1982). In fact, increased phophatase activity was acid observed in Leu-II+ cells which were exposed to higher doses of LPS. Dense granules contain

lysosomal enzymes such as acid phosphatase and arylsulfatase (Kang et al., 1987a; Zucker-Franklin et al., 1983; Babcock and Phillips, 1983) which are believed to be involved in NK cell mediated cytolyis of target cells (Neighbour et al., 1982; Nocera et al., 1983; Frey et al., 1982; Carpen et al., 1981, 1982; Zucker-Franklin et al., 1983). Increase in the number of dense granules may facilitate the lytic ability of NK cells.

Results from the present study showed that rIL-2 significantly enhanced cytotoxicity against K562 target and caused increase of dense granules, hypertrophy of Golgi apparatus and rough endoplasmic reticulum. and mitosis Leu-II cells. Similar observations of the feeect of rIL-2 on the ultrastructure of NK cells were also recently reported in LGL (Zarcone et al., 1987). All these ultrastructural changes are believed to be implicated in the enhancement of NK cytotoxicity as described earlier. In addition, we have recently observed that rIL-2 also enhances the binding of

Leu-ll effectors to K562 target cells (Carl et al., 1987).

Although both IFN-r and rIL-2 have been reported to enhance NK cytotoxicity, the ability of IL-2 to directly affect the cytolytic activity of NK cells has been controversial. Ortaldo et al. (1984) and others (Shiiba et al., 1984; Weigent et al., 1983) reported that the enhancement of cytolytic activity in NK cells by IL-2 is a consequence of triggering IFN-r production. On. the other hand, Trinchieri et al. (1984) and other investigators (Svedersky et al., 1984; Van de Griend et al., 1986; Kabelitz et al., 1985) suggested that IL-2 сf induced enhancement NK cytolytic activity is IFN independent since antibodies against IFN-r do not prevent enhancement of cytolytic activity by IL-2.

In summary, results from the present studies indicated that: (1)both L.P.S and rIL-2 effectively enhance cytotoxicity in PBMC against K562 tumor cells; (2) both LPS and rIL-2 cause similar ultrastrucchanges in Leu-II+ NK tural cells, these changes correlate with NK activity; (3) the effect of LPS on the enhancement of NK cytotoxicity may be a direct and/or indirect process; (4) interferon is implicated in the augmentation of cytotoxicity by LPS.
